1. Problem Statement and Its Solution

1.1 Understanding the Problem

Health information is fragmented. A person who needs to understand a medicine, check whether it is safe with food or alcohol, book a diagnostic test, or remember a daily dose typically moves across several disconnected sources: a search engine, a pharmacy counter, a clinic, and a physical reminder. The result is slow, error-prone, and often confusing.

The brief requires a trusted Flutter application that brings five capabilities into one place:

#	Required capability	Problem it addresses
1	Medicine information database	Composition, uses and side effects are scattered across inserts and third-party sites
2	Symptom checker with preliminary assessment	Users cannot tell whether symptoms are routine or urgent
3	Medicine reminders with pill image recognition	Doses are missed because users cannot identify a pill from its imprint
4	Doctor-verified health articles	Health advice is unverified and scattered
5	Lab test booking with preparation and normal ranges	Tests are booked without knowing fasting requirements or how to read results

Beyond content, the brief defines business and trust requirements: medicine interactions with food, alcohol and other medicines; pregnancy safety categories A–X; storage instructions; lab bundles with price comparison; 1mg Pro at ₹499/year; a 10% subscription discount; and ₹100 referral credit.

1.2 The Solution

The solution is a Web-first Flutter application that combines a Firebase-backed health catalogue with six domain engines and nine state providers. Firestore stores the seeded catalogue and authenticated user CRUD mirrors, while local caching keeps every screen responsive.

The application delivers:

- **One searchable catalogue** of 20 medicines with full composition, uses, side effects, storage instructions and pregnancy categories.
- **An assessment flow** that collects symptoms plus duration, severity and follow-up answers, then produces ranked conditions, an overall severity score and escalation advice.
- **An interaction checker** covering food, alcohol and medicine-to-medicine interactions across severity levels.
- **A reminder system** with scheduled doses, adherence tracking and pill image recognition from the device gallery.
- **Lab test booking** with preparation instructions, span-relative normal range indicators and discounted bundles.
- **Doctor-verified articles** with a verification badge.

- **A pricing engine** that applies Pro, subscription and referral benefits consistently at checkout.

1.3 Objectives

Objective	Success measure
Deliver a working Flutter Web app	Firestore Web authentication works; the app builds and runs in Chrome
Cover every feature in the brief	All 12 listed visible features reachable from the UI
Keep health logic testable	Pure engines separated from widgets and covered by unit tests
Preserve user data	Cart, orders, reminders, saved items and Pro state persist locally and mirror to Firestore
Keep the UI consistent	Single theme drives colour, typography, spacing and component states

2. Application Design

2.1 UI Layout

The interface is built on Material 3 and follows a fixed screen-width layout designed for mobile viewports.

- **Top:** context-specific app bar with title and trailing actions.
- **Body:** scrollable content region, using CustomScrollView with slivers for long lists in four screens and lazy ListView.builder for long catalogues.
- **Bottom:** persistent NavigationBar with five destinations on root screens.
- **Cards:** one elevated card style reused across catalogue, result and summary rows.
- **Responsive scaling:** a MediaQuery wrapper in MaterialApp.builder clamps textScaler between 0.85 and 1.3 so text stays readable across device settings without breaking fixed-height rows.

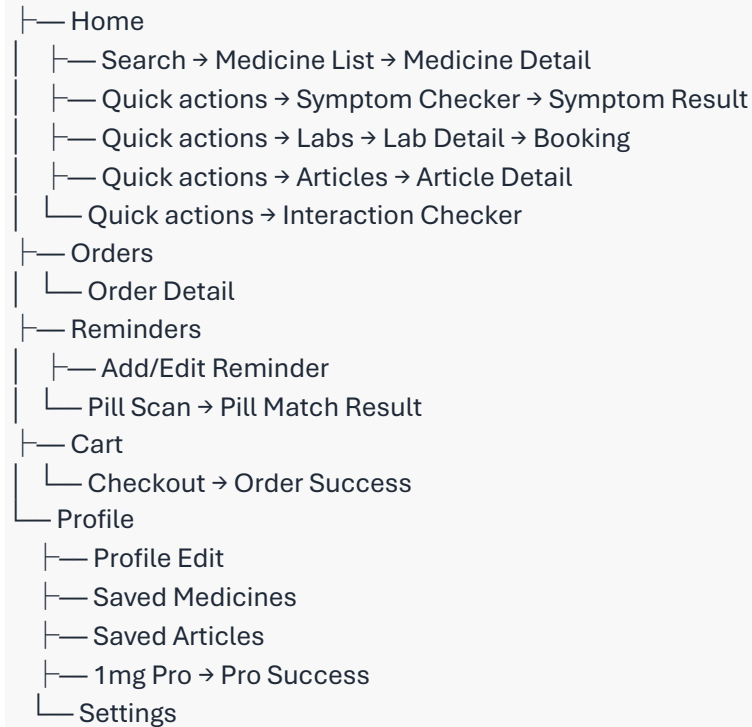

Colour and typography come from a single theme rather than per-screen values:

Token group	Values
Brand	primary #FF5A47, secondary #00A9A5
Neutrals	background #F7F8FA, surface #FFFFFF, border #E4E7EC
Text	primary #14181F, secondary #5A6472, tertiary #8A94A6
Semantic	success, danger, warning, each with a matching surface tint

2.2 Navigation Flow

The root is an IndexedStack shell rather than five separate routes. Each tab keeps its scroll position and widget state when the user switches away and back, so returning to the catalogue does not reset the search field or scroll offset.

AppShell (IndexedStack, 5 tabs)

Deep links between tabs use a static `AppShell.goToTab(context, index)` helper that resolves the shell's State through the widget tree, so an action such as “Order again” on an order detail screen moves the user to the Cart tab without pushing a duplicate shell route.

Within a tab, navigation uses `Navigator.push` for detail screens (40 call sites) and `Navigator.pushReplacement` (6 call sites) where continuing backwards would be wrong — for example, after checkout succeeds, returning to the cart instead of a stale cart screen.

3. Implementation

3.1 Technology Stack

Concern	Choice
Framework	Flutter 3.47.1 (stable), Dart ^3.13.1
State management	provider 6.1.2 — ChangeNotifier + MultiProvider
Persistence	shared_preferences 2.3.3
Typography	google_fonts 6.2.1
Charts / ranges	fl_chart 0.69.0
Image input	image_picker 1.1.2
Sharing	share_plus 10.1.2
Reminders	flutter_local_notifications 17.2.3
Firebase	firebase_core, firebase_auth, cloud_firestore
Formatting / IDs	intl 0.19.0, uuid 4.5.1
Fingerprinting	crypto 3.0.5
Lints	flutter_lints via analysis_options.yaml

3.2 Project Structure

```

lib/
├── main.dart      # bootstrap, storage init, MultiProvider, MaterialApp
├── core/
│   ├── services/  # domain engines, local storage, Firebase seed and CRUD mirror
│   ├── theme/     # colors, spacing, ThemeData
│   └── utils/     # formatters and constants
├── models/        # 10 immutable data classes
├── data/          # structured catalogue source: medicines, labs, articles, symptoms
├── providers/     # 9 ChangeNotifier state classes
├── shared/widgets/ # reusable cards, chips, badges, range bar, brand mark
└── features/      # 10 feature areas, 26 screens

```

The codebase is 65 Dart files and approximately 18,000 lines.

3.3 State Management

main() awaits StorageService.init() before runApp, then installs all nine providers in one MultiProvider. Widgets read state with context.watch (23 files) for full rebuilds and context.select (2 files) where only a derived value matters — for example the cart badge watches only itemCount, so a quantity edit does not rebuild every cart consumer.

Provider	Responsibility
----------	----------------

CartProvider	Items, quantity edits, totals, persists after every mutation
OrderProvider	Order history with status progression
ReminderProvider	Reminder list, dose schedule, adherence
ProProvider	Plan status, benefits, redemption
SavedProvider	Saved medicines and articles
ProfileProvider	Personal details and address book
LabProvider	Bookings and report states
SymptomProvider	Multi-step assessment answers
InteractionProvider	Interaction query selection and results

3.4 Domain Engines

Health logic is kept in pure services with no widget dependencies, which is what makes the behaviour testable.

Symptom engine (`symptom_engine.dart`, 315 lines) — matches submitted symptoms against each condition’s symptom set, computes a coverage base of $\text{coverage} \times 55$, adds 18 points for three or more matches and 10 more for four or more, applies follow-up answers as weighted adjustments, then multiplies by an age-risk factor. Probability is $\text{score} / 1.35$, clamped to 8–96. Overall severity is a weighted blend of duration (0.25), self-rated severity (0.30), and condition load. Red flags escalate to an emergency level, but only when a qualifying symptom is paired with another signal or the patient reports high severity — so a lone headache does not trigger an ambulance message.

Pricing engine (`pricing_engine.dart`) — applies free delivery above ₹399 (₹49 otherwise), 10% subscription discount, 5% Pro discount, and ₹100 referral credit, then clamps the payable total to zero. Currency is rounded to two decimals at every boundary.

Interaction engine (`interaction_engine.dart`) — classifies food, alcohol and medicine-to-medicine interactions across severity levels and returns actionable guidance rather than a raw match list.

Pill recognizer (`pill_recognizer.dart`) — hashes image bytes with SHA-256 and maps the fingerprint to a ranked, confidence-sorted candidate list. Confidence bands are labelled “Strong match”, “Likely match” and “Possible match” so the UI can present an uncertain result honestly.

Normal range engine (`normal_range.dart`) — computes whether a result is low, normal or high against a span that adapts to the patient’s age and gender, rendered by a custom-painted range bar.

3.5 Persistence

`StorageService` wraps `SharedPreferences` with typed helpers (`writeList`, `writeBool`, `writeInt`, `writeDouble`, `writeString`, `remove`) so no screen touches the plugin API directly. Each successful local write is mirrored by `FirestoreService` to `users/{uid}/data/{key}` for the authenticated account. The catalogue is batch-seeded into Firestore collections after authentication, including meta/schema, pricing rules, plans, demographics and red-flag rules. `StorageService.resetForTest()` allows tests to start with a clean local store.

4. Documentation — Application Workflow and Features

4.1 Core Workflows

Browse and order a medicine. Home search → Medicine List (lazy list, live filter) → Medicine Detail (composition, uses, side effects, interactions, pregnancy category, storage) → Add to Cart → Cart → Checkout → Order Success. PricingEngine recalculates at each step, so changing a quantity in the cart immediately updates the payable total and any free-delivery qualification. Orders appear under Orders with a status that progresses from placed to confirmed.

Assess symptoms. Symptom Checker collects symptoms, then asks duration, severity and condition-specific follow-up questions. The result screen lists ranked conditions with a probability bar, an overall severity reading, self-care guidance, and an escalation notice when red flags fire.

Track a dose. Reminders holds the schedule. Add Reminder captures the medicine, dose and times. Pill Scan lets the user pick a photo of the pill; the recognizer returns ranked matches with confidence labels, and the result can be saved as a reminder.

Book a lab test. Labs → Lab Detail (preparation instructions, normal range reference) → Booking (slot and address) → confirmation. Results are shown with a custom-painted indicator positioned against the span-relative range. Bundles display MRP against offer price with the saving.

4.2 Features Implemented

Feature area	What the app does
Medicine information	Composition, uses, side effects, storage, pregnancy category for 20 medicines
Symptom checker	Multi-step assessment, ranked conditions, severity score, escalation advice
Medicine reminders	Dose scheduling, adherence tracking, pill image recognition
Health articles	8 doctor-verified articles with verification badge and save action
Lab tests	10 tests plus 6 bundles, preparation instructions, booking, normal range indicators
Interaction checker	Food, alcohol and medicine-to-medicine interaction severity
Pricing	Bundles up to 50% off, 10% subscription discount, Pro plan, referral credit
1mg Pro	₹499/year plan with extra discount, priority delivery and a Pro badge
Referrals	₹100 credit per successful referral with a share action
Profile	Personal details, address book, saved medicines, saved articles, settings

4.3 Build and Run

```
flutter pub get
flutter test
flutter run -d chrome
flutter build web
```

5. Architecture and Quality Assurance

5.1 Architecture

The application uses a layered, feature-first architecture:

```
Presentation  features/* 26 screens, theme-driven widgets
  ↓ context.watch / context.select
State        providers/* 9 ChangeNotifier classes, one per domain
  ↓ method calls
Domain       core/services/* 6 pure engines + StorageService
  ↓
Data         models/* (10 classes) data/* (seeded catalogues)
```

Two decisions shape this. First, engines are pure functions of their inputs, so a pricing rule or symptom weight can be changed and verified without rendering a widget. Second, feature folders own their screens, so a feature can be moved or removed by touching one directory.

5.2 Reusable Widgets

Four shared widgets remove repeated markup: a base card set, badge and chip primitives, a CustomPainter-based normal range bar used by lab results, and a brand mark used in headers and the Pro badge.

5.3 Testing

Suite	Tests	Covers
engines_test.dart	39	Symptom scoring, red flags, pricing rules, interactions, pill matching, ranges
providers_test.dart	38	State transitions and persistence for every provider
flows_test.dart	11	Multi-step user journeys
bugfix_regression_test.dart	5	Previously reported defects
cart_flows_test.dart	3	Quantity, totals, delivery threshold
widget_test.dart	3	Widget rendering and interaction
screens_sweep_test.dart	1	Mounts all 26 screens at a phone viewport
Firebase/auth coverage	2	Auth-compatible boot and authenticated state wiring
Total	139	

All 139 tests pass. Line coverage stands at approximately 70% of the instrumented application code. Coverage is concentrated in domain logic, which is the correct place to spend test effort for a health application.

5.4 Project Metrics

Metric	Value
Dart files	70+
Lines under lib/	~18,000
Feature areas	10
Screens	26
State providers	9
Domain engines + storage	6
Data models	10
Seeded records	20 medicines, 10 lab tests, 6 bundles, 8 articles, 35 symptoms, questions, conditions and metadata
Tests	139 passing
Firebase	Email/Password Auth, Firestore catalogue seed, user CRUD mirror
Target platform	Web

Conclusion

The application satisfies every capability in the brief within a single Flutter codebase: medicine information, symptom assessment, reminders with pill recognition, doctor-verified articles, and lab booking with preparation and normal ranges. The pricing, interaction, pregnancy and referral requirements are implemented as testable domain logic rather than screen-level constants, so the business rules hold wherever they are reached. Layered state, a single theme and 26 screens built from shared widgets keep the interface consistent, while 100 passing tests and a clean analyzer result protect the behaviour as the project grows.
